ACC NR: AF6030081

mating the degree of reliability of the results. Plots are presented of the relative fraction of the multiple scattering in the brightness of the twilight sky obtained for different observation directions by various theoretical methods suggested by others and from the authors' experiments. It is indicated that a detailed analysis of the twilight brightness observations yields reliable estimates of the brightness of the secondary scattered light by the atmosphere without making additional hypotheses concerning the optical structure of the atmosphere, provided the volume of photometric information is sufficient. A relation for the secondary brightness intensity is obtained for both the near-zenith region and for the region near the countervertical of the sun. It is also shown that the authors' earlier measurements make it possible to utilize simultaneously the two independent methods proposed by G. V. Rozenberg (Sumerki [Twilight], Fizmatgiz, 1963) (find the instantaneous brightness gradient along the solar meridian and find the rate of change of brightness at a given point in the sky) for the determination of the height variation of the scattering coefficient of the atmosphere from data on the brightness of the twilight sky. It is recommended on the basis of the results that the twilight sounding method is preferred for the height interval from 30 to 110 km, and that both methods should be employed simultaneously. [02]

TITLE: Detector of linear motion of parts. Class 83, No. 176524

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 22, 1965, 96

TOPIC TAGS: aircraft fuel system equipment, hydraulic equipment

ABSTRACT: This Author Certificate presents a detector of linear motion of the equipment parts, and principally of the translational motion time in the slide rod of hydraulic systems in automatic aviation fuel equipment. The measured part has a hole intersecting a light beam incident on a photometric detector. To increase the accuracy of measurement and to insure a given constant force of motion of the slide rod for the whole measured section of travel, the hydraulic drive has a rigidly coupled screen and rod, which have different reference cross-sectional areas (see Fig. 1). The photometric detector with two photodiodes has a slotted shield for limiting the light beam and adjusting the detector to the initial point of command

USER/Miscellaneous - Communication-work planning

Card 1/1 Pub. 133 - 9/23

Authors : Pylev, V. V., Head of the District Communications Office of the city of Romny, Sumy Region; and Bol'shakova, E. M., Senior Economist

Title : The deficiencies in planning and evaluating economic factors of managing local communications offices must be eliminated

Periodical : Vest. svyazi 8, 14-15, Aug 1954

Abstract : The author describes the difficulties encountered by the Romny District Communications Office when, according to instructions received from the Central Regional Office, its work was reorganized on a self-paying basis instead of being operated on government subsidies. The defects connected with new planning are analyzed and methods for their elimination proposed.

✓ Supercooling two-component saturated solutions. E. I. Akhunov and E. V. Pylkova (V. I. Ul'yanov-Lenin Electro-
tech. Inst., Leningrad). *Doklady Akad. Nauk S.S.R.* 108, 857-60 (1956). — The max. supercooling is discussed in
the NaCl-H₂O, KCl-H₂O, and KNO₃-H₂O systems, obtained
after a previous superheating. The method used was de-
scribed by A. and co-workers (*C.A.* 27, 219; 31, 2524*).
The heating and cooling conditions were carefully controlled.
The results of av. values of max. supercooling in the 3 two-
component systems are presented in a table, and confirm
the theoretical relation derived by A. and Rozen (*C.A.* 48,
9790*).

✓ W. M. Sternberg

Method for the preparation of the standard uranium oxide and the determination of its saturation current. A. N. Pygagov. *J. Gen. Chem. (U. S. S. R.)* 1, 133-42 (1931). About 300 g. of U-V O_2 was dissolved in dil. HCl. Only 10% of silica was left undissolved, contg. Th and Act. At the same time Ra, M₂Th, Ra-Th and partially U-X and U were sepd. by BaCl₂. BaSO₄ was pptd. with very dil. H₂SO₄. Thereupon the ppt. was carefully filtered, the filtrate was treated with Bi(NO₃)₃ and Pb(NO₃)₂, and std. with H₂S and CuS. Bi₂S₃ and PbS with adsorbed Ra D, Ra F and Ra G were filtered off. The heavy metals such as Fe, Mn, U and V, reduced by H₂S, were oxidized again with Br, pptd. with NH₄OH free from CO₂, and filtered. The ppt., well washed with dilut. water, was treated either (1) with a soln. of (NH₄)₂CO₃ or (2) with HNO₃; the soln. was evapd. to dryness and uranyl nitrate was extd. by ether. To be certain that the salt is radiologically pure it was purified according to the method of Widdowson and Russel (*C. A.* 18, 351). It was very difficult to get the green U_3O_8 from which U X, was sepd. not more than 24 hrs. later. The substance was placed in an electro scope and its current was measured for 3 months. The increase of U X followed closely the theoretical curve. The satn. current of green U_3O_8 on the surface of 1 cc. was detd. afterward. V. D. KARSKO

Preparation of standard solutions of thorium chloride and its disintegration products. A. N. Polikar'ev, T. G. Tsvetkov, standardization U. R. S. S. 1966, No. 6, 3-10 (in French 11-12).—For the purpose of standard ThCl₄ solution, the ore must be free from U and its disintegration products. In Russia the uranites (allanites) found in the Urals and Altai are most suitable for this purpose. The formula for allanite is (SiO₄)₂Ca₂U(OH)₆. No U could be detected in this ore by chem. means. Finely ground crude ore (100 g.) was treated with 200 cc. aqua regia. After removal of Na, K, Fe, Ca, Mg and the rare earths, the ThCl₄ solution were standardized by the emanation method.

TITLE: Solubility and Supersaturation in the System Sodium Sulfate-Water at High Temperatures (Rastvorimost' i peresyshcheniye v sisteme sul'fat natriya-voda pri vysokikh temperaturakh)

PERIODICAL: Zhurnal neorganicheskoy khimii, 1958, Vol 3, Nr 9, pp 2178-2183
(USSR)ABSTRACT: The solubility and supersaturation in the system of sodium sulfate - water was examined at a temperature of 233°C. The analyses were carried out by polythermal methods. The crystallization in the system $\text{Na}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ depends on the composition of the initial solutions when temperature varies. The results of experiments with saturated and supersaturated solutions of aqueous sodium sulfate at higher temperatures make it possible to draw the phase diagram of this system. It can be seen from the phase diagram that there are three meta-stable branches at temperatures of more than 233°C. The interdependence between the negative absolute temperatures of crystallization of the saturated solution T_1 and the supersaturated temperature of crystallization T_2 was represented graphically. Various rhombic

Orig Pub: Sb. stud. nauchn.-issled. rabot Mosk. s.-kh. akad. im. K. A. Timiryazeva, 1956, vyp. 6, 3-9

Abstract: The cross between the Blokadnaya (erythrospermum) and the Diamant varieties which differ in quantitative characteristics and are similar in development is most promising, especially in productivity and the quality of the grain. Those forms obtained through crossing which belong to the ferrugineum and lutescens varieties are less productive than the developed forms of the parental varieties. In

Orig Pub: Klinich. meditsina, 1957, 35, No 7, 98-102.

U

Abstract: The authors describe three personal observations of extra medullary lung plasmocytomas and analyzed 8 cases in the world of literature. The tumor was more frequently situated in the upper lobes of the lung, in the form of an isolated structure inclosed in a thin capsule. On section, the tumor appeared white-yellowish or gray-yellowish in color, was fragile, and consisted of mature plasma cells of 10-12 microns in diameter.

TITLE: Domain structure of cobalt films grown on NaCl crystals /Transactions of the
Second All-Union Symposium on the Physics of Thin Ferromagnetic Films held at Irkutsk
10 July to 15 July, 1964/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v.30, no.1, 1966 34-36

TOPIC TAGS: ferromagnetic film, magnetic thin film, cobalt, magnetic domain structure,
magnetic anisotropy

ABSTRACT: Cobalt films were deposited at 10^{-4} mm Hg on NaCl crystal cleavage surfaces
having temperatures from room temperature to 400°C , and their domain structures were
observed by means of a transmission electron microscope. Conditions for obtaining
single-crystal films are reported in another communication. Films deposited on sub-
strates at 20°C contained hexagonal, cubic and amorphous phases and had a domain
structure that was initially mottled and developed under the influence of an ac field
into a structure of coarse domains with weakly developed substructure. The mottled
domain structure is ascribed to the presence of nonmagnetic inclusions. Films de-
posited on substrates heated to 70 to 150°C did not show a mottled domain structure.

Cord 1/2

L 15385.66

ACC NR: AP6004462

but the substructure was strongly developed. It was possible to obtain oriented films of β -cobalt crystallites on a 200° substrate. The domain structure of these films showed no substructure. Investigation of the domain structure of the oriented films showed that films of cubic cobalt deposited from molybdenum or tungsten crucibles at 10^{-4} mm Hg have positive magnetic anisotropy, with an anisotropy constant about an order of magnitude less than that of iron. This finding contradicts the results of H. Sato, K. S. Toth, and R. W. Astrue (J. Appl. Phys., 34, 1062 (1963)). Films deposited on substrates heated to 300°C and above had a mottled domain structure which is ascribed to the presence of nonmagnetic inclusions consisting, in this case, of voids. TITLE: Epitaxial films of iron, nickel and cobalt [report presented at the Conference on Physics of Ferro- and Antiferromagnetism, Sverdlovsk, 5-7 July 1965]

SOURCE: Fizika metallov i metallovedeniye, v. 22, no. 3, 1966, 380-391

TOPIC TAGS: magnetic anisotropy, epitaxial growing, hysteresis loop, metal film

ABSTRACT: The authors study the epitaxial growth of iron, nickel and cobalt films thermally vaporized onto ionic crystals split in air and in a vacuum. It is shown that when the substrates are heated in a vacuum of 10^{-4} mm Hg, the surface state is changed with a favorable effect on epitaxy. The phase composition of the film may be controlled by proper selection of the substrate. The fields of anisotropy of the films are measured and the effect which application of a magnetic field during vaporization has on the magnetic anisotropy of the films is studied. The domain structure of the films and its dynamics are analyzed and the results are used as a basis for explaining the shape of hysteresis loops. The coercive force is measured in films of various thickness. It is shown that the coercive force of the films is always much less than the field of anisotropy and is approximately inversely proportional to the saturation magnetization. Orig. art. has: 13 figures, 1 table, 5 formulas.

TITLE: Single-crystal films of iron-nickel alloys (Transactions of the Second All-Union
Symposium on the Physics of Thin Ferromagnetic Films held at Irkutsk 10 July to
15 July 1964)

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v.30, no. 1, 1966, 50-53 and insert
(facing page 45)

TOPIC TAGS: ferromagnetic film, magnetic thin film, permalloy, iron nickel alloy,
single crystal, magnetic anisotropy; magnetic coercive force, magnetic domain structure.

ABSTRACT: Single-crystal 800 Å films of Fe-Ni alloys (5 to 95% Ni) were obtained by
vacuum evaporation at 10^{-3} to 10^{-4} mm Hg onto the heated (250 to 400°C) surface of an
NaCl crystal, although O.S.Heavens (Proc. Phys. Soc. 78, 33 (1961)) and A.Baltz (J.
Appl. Phys., 32, 815 (1961)) found that high vacuum (10^{-9} mm Hg) and annealing was neces-
sary to obtain single-crystal films. No reason for this discrepancy is suggested. The
alloys containing less than 20% Ni crystallized in a body-centered lattice with a
lattice constant of 2.828 Å and grew with the (001) face and (100) axis parallel to
the (001) face and (110) axis, respectively, of the NaCl substrate; the alloys con-

Card 1/2

L 17409-66

ACC NR: AP6004466

taining more than 20% Ni crystallized in a face-centered cubic lattice with a lattice constant of 3.576 Å and grew with the (001) face and <100> axis parallel to the (001) face and <100> axis, respectively, of the substrate. Microtwinning was observed. The single-crystal films had two mutually perpendicular easy magnetization axes, this was not observed by S;Chikazumi (J. Appl. Phys., 32, 815 (1961)). The anisotropy constant was positive for films containing up to 79.4% Ni and was negative for films containing 82% Ni or more. The coercive force depended strongly on the temperature of the substrate during deposition; the coercive force of films of an undisclosed composition increased from 9 to 80 Oe as the temperature of the substrate during deposition was increased from 250 to 350C. Films deposited at temperatures below 250C were polycrystalline. The single-crystal films either consisted of a single domain with substructure, or were mottled. After demagnetization in a decreasing ac field parallel to the hard axis the films had 90° domain walls in the direction of the hard axis and 180° walls in the direction of the easy axis. When a mottled film was demagnetized along the easy axis, the spots became aligned along substructure lines; when the same film was demagnetized along the hard axis there appeared domain walls consisting of separate points. The presence of substructure makes it possible to determine the directions of the easy axes. The easy axis directions determined from the substructure agreed with those determined from the shapes of the hysteresis loops. Orig. art. has: 5 figures.

facing p. 94 and 95TOPIC TAGS: ferromagnetic film, magnetic thin film, magnetic domain structure,
magnetic anisotropy, magnetic coercive force,ABSTRACT: The coercive forces in directions forming angles of 0, 25, and 45° with an
easy axis of a film with strong biaxial magnetic anisotropy are calculated on the basis
of a model according to which switching takes place by processes of formation and dis-
placement of 90° domain walls. The model adopted for switching at 25° to an easy axis
involves successive formation and displacement of two sets of 90° walls and leads to
two values of the coercive force. The presence of two values of the coercive force is
revealed by steps in the hysteresis loops of epitaxial iron films. The calculated

Card 1/2

27 144.5

L 15423-66

ACC NR: AP6004478

coercive forces are compared with experimental values derived from hysteresis loops. The calculated coercive forces were normalized to agree with the experimental value for 0° inclination to an easy axis, and good agreement between theory and experiment is shown for the remaining three values (two at 25° and one at 45°). It is concluded that the coercive force of films with strong biaxial magnetic anisotropy is due mainly to domain wall displacement and not to nucleation. TITLE: Observation of the domain structure of thin ferromagnetic films by an EM3 electron microscope

SOURCE: Pribory* i tekhnika eksperimenta, no. 1, 1964, 178-179

TOPIC TAGS: ferromagnetic film, domain structure, ferromagnetic film domain structure, electron microscope, EM3 electron microscope

ABSTRACT: A Soviet-make EM3 electron microscope was modified for the purpose of observing the domain structure of iron-nickel and cobalt thin films prepared by powder spraying. With the microscope objective turned off, enlargements up to 400 were possible with only a low resolution. With the objective lens on, satisfactory visual observation was obtained with enlargements up to 1,000 and a much better resolution. "The author wishes to thank

TITLE: Anisotropy of epitaxial cobalt films

SOURCE: AN SSSR. Doklady, v. 164, no. 6, 1965, 1267-1268, and bottom half of insert facing page 1260

TOPIC TAGS: cobalt, magnetic thin film, epitaxial growth

ABSTRACT: Fully oriented cobalt films may be obtained at 10^{-4} mm Hg by thermal spray-coating of freshly cleaved NaCl crystals heated to 200°C. The present investigation of the domain structure and hysteresis loops of such films shows that they have an unstable axis of easy magnetization. Theoretical consideration shows that the presence of α -phase crystallites within the epitaxial cobalt film seems to decrease the negative anisotropy, and if such crystallites are present in sufficient quantities, they could create a "positive" total anisotropy, such as in films deposited on NaCl crystals. No such α -phase crystallites could be observed on cobalt films deposited on LiF crystals at 250°C the anisotropy of which is always negative. This is evidence in favor of the hypothesis that the α -crystallites with an increased oxygen content are responsible for the appearance of "positive" anisotropy. This is in agreement with the results

TOPIC TAGS: ferromagnetic film, magnetic thin film, iron, epitaxial growth, sodium
chloride, magnetic domain structure

ABSTRACT: The domain structure of 600 to 1000 Å epitaxial iron films vacuum deposited
on NaCl substrates was investigated by electron microscopy and by the powder pattern
technique. The growth and crystal structure of the films are discussed elsewhere by
V.G. Pyn'ko and R.V. Sukhanova (Izv. AN SSSR, Ser. fiz., 30, 43 (1966); see Abstract
AP6004464/). The films were transferred in water from the NaCl substrate to glass
for examination by the powder pattern technique or to 50 x 50 µ grids for examination
with the electron microscope. The films could be roughly classified into three types:
1) fully oriented films with the (001) plane in the plane of the film; 2) films with

Card 1/2

L 15374-66

ACC NR: AP6004465

crystallites oriented in two or three different ways with the (001) face in the film parallel to the (001) face of the substrate and the [100] axis in the film parallel to the [110] or the [100] axis in the substrate, or with the (110) face in the film parallel to the (100) face in the substrate and the [100] axis in the film parallel to the [100] axis in the substrate; and 3) films containing a large number of randomly oriented crystallites. It was very difficult to obtain a checkerboard domain structure in type 1) films; under the influence of an ac field there usually appeared large rectangles or squares of different sizes. A regular checkerboard structure was obtained in type 2) and 3) films, but the "squares" were rectangular. These checkerboard structures developed in two stages, the domain walls perpendicular to the ac field forming first. Type 1) films initially had a fine domain structure with 180° and modified 90° walls; type 2) films regularly had an initial mottled domain structure; the initial domain structure of type 3) films was like that of type 1) or type 2) films, depending on the substrate temperature and deposition rate. After demagnetization the domains of type 3) films always showed substructure and those of type 1) films did not. The 180° domain walls were continuous except those in type 3) films containing a large number of randomly oriented crystallites. It is concluded that substructure in epitaxial films is associated with anisotropy dispersion, and that 180° domain walls in epitaxial iron films always have an internal structure which, however, may not appear in the electron microscope image. It was not possible to observe the domain structure of the 600 Å films. Orig. art. has: 4 figures.

TITLE: Domain structure and switching of single-crystal nickel films (Transactions
of the Second All-Union Symposium on the Physics of Thin Ferromagnetic Films held at
Irkutsk 10 July to 15 July, 1964)

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 1, 1966. 91-92

TOPIC TAGS: ferromagnetic film, magnetic thin film, nickel, magnetization, single crystal, magnetic domain structure, epitaxial growing, sodium chloride

ABSTRACT: Nickel films from 200 to 1200 Å thick were deposited on NaCl substrates at 120°C, the minimum temperature for epitaxy, and their domain structures and dynamics were investigated. The (001) planes and [100] axes of the epitaxial films were parallel to the (001) planes and [100] axes, respectively, of the substrates. The easy axis in the plane of the film was in or close to the [110] direction. Epitaxial nickel films deposited on NaCl at higher temperatures usually have a fine mottled domain structure and switch by nonuniform rotation. The domain structure of the "cold" films and their switching behavior varied with the thickness. The domains of

Card 1/2

L 15377-66
ACC NR: AP6004477

the films thicker than 500 Å exhibited substructure and the walls evinced a complex internal structure. Domain formation took place over the full area of the film and switching was accomplished by domain destruction without significant wall movement. These films were characterized by inclined hysteresis loops. This behavior is ascribed to inclination of the easy axis to the plane of the film, owing to the absence in that plane of a [111] axis. The easy axis of a film from 300 to 500 Å thick lay in the plane of the film in the [110] direction. These films were rather uniform and amplitude dispersion of the anisotropy was not detected. The domains were large and domain wall movement played a significant role in the switching process. Switching of films less than 300 Å thick began with the appearance of substructure owing to the nonuniform rotation of the magnetization. The behavior of these films is ascribed to amplitude dispersion of the anisotropy due to nonuniform thickness of the film. Orig. art. has: 4 figures.

ACCESSION NR: AP4046045

the Faraday-magneto-optical effect (C. A. Fowler and E. M. Fryer, J. Appl. Phys. 24, 104, 1953). The magnetization reversal was carried out at various angles between the magnetization-reversal field and the easy magnetization direction [100]. Demagnetization by a gradually decreasing alternating field causes the domain structure to break up into a series of plane-parallel domains elongated in one of the directions of the easy magnetization. Demagnetization in the difficult magnetization direction [110] results in a system of domains with 90° boundaries (a checkerboard domain structure). Magnetization reversal at intermediate

TITLE: Epitaxial growth of films of silver, copper, and nickel on
NaCl crystals cleaved in vacuum.

SOURCE: Fizika tverdogo tela, v. 8, no. 3, 1966, 971-972

TOPIC TAGS: epitaxial growing, metal film, silver, copper, nickel,
ultrahigh vacuum

ABSTRACT: To explain the causes of experimentally observed differences in the epitaxial growth of metal films in high and ultrahigh vacuum, the author sets up an experiment wherein the substrate crystals for the films were cleaved in a vacuum chamber (Fig. 1). The apparatus made it also possible to vary the time τ between the instant of cleavage of the crystal and the start of deposition of the film. Electron diffraction patterns have shown that an increase in τ leads
